A Perfect Calibration ! Now What ? Model Risk for Exotic and Moment Derivatives

Wim Schoutens, Erwin Simons[†] [‡]tastaert[‡]

Cambridge, 3rd of December 2004

www.schoutens.be

Abstract

We show that several advanced equity option models incorporating stochastic volatility can be calibrated very nicely to a realistic option surface. More specifically, we focus on the Heston Stochastic Volatility model (with and without jumps in the stock price process), the Barndorff- Nielsen-Shephard model and Lévy models with stochastic time. All these models are capable of accurately describing the marginal distribution of stock prices or indices and hence lead to almost identical European vanilla option prices. As such, we can hardly discriminate between the different processes on the basis of their smile-conform pricing characteristics. We therefore are tempted applying them to a range of exotics. However, due to the different structure in path-behaviour and the underlying dependency over time between these models, the resulting exotics prices can be significantly different. It motivates a further study on how to model the fine stochastic behaviour of assets over time.

Samuelson/Black-Scholes Model (1965-1973)

GEOWELKIC BKOMNINN WOLION WODEL:

$$0 < x = {}^{0}S \qquad ``^{t}Mp + \tau p \eta = \frac{{}^{t}S}{{}^{t}Sp}$$

This SDE has a unique solution:

$$\cdot \left({}^{t} M \mathcal{O} + \mathfrak{I} \left(\frac{\zeta}{\zeta^{\mathcal{O}}} - \eta \right) \right) \mathrm{dx}_{\partial} \, {}^{0} S = {}^{t} S$$

Figure 1: Sample path of a geometric Brownian motion $(S_0 = 100, \mu = 0.05, \sigma = 0.4)$

Note that the log-returns are normally distributed: $\log S_t - \log S_{t-1} \sim \text{Normal}\left(\mu - \frac{\sigma^2}{2}, \sigma^2\right).$

The Normal density is not a good approximation of the empirical density.

Lévy Models (1990) • Instead of taking normally-distributed log-returns, we now model the stock price/index

(0661) гіром үчэл

Examples of models

- \bullet 1990: Madan and Seneta: Variance Gamma Process
- 1995: Eberlein and Keller: Hyperbolic model
- 1995: Barndorff-Nielsen : Normal Inverse Caussian model
- 2000: Carr, Madan, Geman and Yor : The CGMY model
- \bullet 2000: Grigelionis, Teugels, Schoutens : The Meixner model

Example: The Meixner Process

The characteristic function of the Meixner (α, β, δ) distribution is given by

$$\phi_{M \in ixn \in r}(n; \alpha, \beta, \delta) = \left(\frac{\cosh \frac{2}{\alpha n - 1\beta}}{\cos(\beta/2)} \right)^{2\delta}$$

The above Lévy process are pure jump process : Jumps of size in some set $A \subset \mathbb{R}$ occur according to a Poisson Process with parameter given by the Lévy measure of A. For the Meixner case:

$$xp\frac{(n/x\mu)uis x}{(n/xq)dxa}p^{V} = (xp)n^{V}$$

Empirical Density vs Meixner Density

The Meixner density can be fitted very accurately to the empirical density.

Figure 5: Meixner density and Gaussian Kernel estimator of the density of the daily log-returns of the SP500 index

Pricing of Vanilla Options

Let α be a positive constant such that the α th moment of the stock price exists. Carr and Madan (1998) then showed that

$$\mathcal{O}(K,T) = \frac{\exp(-\alpha \log(K))}{\pi} \int_{0}^{+\infty} \exp(-i\nu \log(K)) \varrho(\nu) \mathrm{d}\nu,$$

мубте

$$\varrho(v) = \frac{\exp(-rT)E[\exp(i(v-(\alpha+1)i)\log(S_T))]}{\alpha^2 + \alpha - v^2 + i(2\alpha+1)v}$$

$$= \frac{\exp(-rT)\phi(v-(\alpha+1)i)}{\alpha^2 + \alpha - v^2 + i(2\alpha+1)v} \cdot$$

The Fast Fourier Transform can be used to invert the generalized Fourier transform of the call price. Put options can be priced using the put-call parity.

Meixner Option Prices

Calibrating the Meixner model prices to the market prices (in the least squared sense) leads to a better but not satisfactory fit of the option surface:

Figure 6: Meixner ($\alpha = 0.3801$, $\beta = 0.3264$) calibration on Eurostoxx options (o's are market prices, +'s are model prices).

There is a need for models who capture both non-normal returns and stochastic volatility:

- \bullet Heston Models (HEST)
- Heston with jumps Model (HESJ)
- \bullet Barndorff-Nielsen Shephard Models (BNS)
- Stochastic Volatility Lévy Models

Iebol vilitsio vilasio vilasio vilasi

• In the Heston-Stochastic Volatility model the stock price process follows the following SDE:

$$0 \leq {}^{0}S \quad {}^{\prime}{}^{*}Mb_{*}\sigma + tbr = \frac{{}^{*}S}{{}^{*}Sb}$$

the (squared) volatility process is also assumed to be stochastic and is following the

$$\mathrm{d}\sigma_{t}^{2} = \kappa(\eta - \sigma_{t}^{2})\mathrm{d}t + \lambda\sigma_{t}\mathrm{d}\tilde{W}_{t}, \quad \sigma_{0} \ge 0,$$

where $W = \{W_t, t \ge 0\}$ and $\widetilde{W} = \{\widetilde{W}_t, t \ge 0\}$ are two correlated standard Brownian motions such that $\operatorname{Cov}[\mathrm{d}W_t \mathrm{d}\widetilde{W}_t] = \rho \mathrm{d}t$.

• The characteristic function $E[\exp(iu\log(S_t))] = \phi(u,t)$ is in this case given by:

$$\phi(u,t) = \mathcal{E}[\exp(iu\log(S_t))|S_{0},\sigma_0^2]$$

$$\approx \exp(\eta\kappa\lambda^{-2}(\kappa-\rho\lambda iu+d)t-2\log((1-ge^{dt})/(1-ge^{dt}))))$$

$$\times \exp(\sigma_0^2\lambda^{-2}(\kappa-\rho\lambda iu+d)(1-e^{dt})/(1-ge^{dt})),$$

мүбге

$$g = (\kappa - \rho \lambda ui - \lambda)/(\kappa - \rho \lambda ui - \lambda) = b$$

HEC1

An extension of HEST introduces jumps in the asset price:

$$\mathrm{d}\sigma_{t}^{2} = \kappa(\eta - \sigma_{t}^{2})\mathrm{d}t + \sigma_{t}\mathrm{d}W_{t} + J_{t}\mathrm{d}N_{t}, \quad \sigma_{0} \ge 0,$$
$$\frac{\mathrm{d}S_{t}}{\mathrm{d}S_{t}} = (r - q - \lambda\mu_{J})\mathrm{d}t + \sigma_{t}\mathrm{d}W_{t}, \quad \sigma_{0} \ge 0,$$

мубте

• $N = \{N_t, t \ge 0\}$ is an independent Poisson process with intensity parameter $\lambda > 0$

swonor
$$t_{\mathbf{C}}$$
 əzis quiul əgəniəərəd ən

$$\log(1 + J_t) \sim N$$
ormal $\left(\log(1 + \mu_J) - \frac{2^2}{2}, \sigma_J^2\right),$

- $W = \{W_t, t \ge 0\}$ and $\tilde{W} = \{\tilde{W}_t, t \ge 0\}$ are two correlated standard Brownian motions such that $\operatorname{Cov}[dW_td\tilde{W}_t] = \rho dt$,

HEC1

The characteristic function $\phi(u,t)$ is in this case given by:

$$\begin{split} \phi(u,t) &= \mathcal{E}[\exp(\mathrm{i}u\log(S_t))|S_0,\sigma_0^2] \\ &= \exp(\mathrm{i}u\log(S_0+(\kappa-\rho\theta_{1}-1)) + 2\log((1-ge^{-dt})/(1-ge^{-dt})))) \\ &\times \exp(\sigma_0^2\theta^{-2}(\kappa-\rho\theta_{1}-d)(1-e^{-dt})/(1-ge^{-dt})), \\ &\times \exp(\sigma_0^2\theta^{-2}(\kappa-\rho\theta_{1}-d)(1-e^{-dt})/(1-ge^{-dt})), \\ &\times \exp(-\lambda\mu_{1}\mathrm{i}t + \lambda t((1+\mu_{1}))\mathrm{i}^{u}\exp(\sigma_{1}^2(\mathrm{i}u/2)(\mathrm{i}u-1))), \\ \end{split}$$

where d and g are as in given above.

The BN-S Model (general case)

 \bullet In the BN-S model the squared volatility now follows a SDE of the form:

$$\mathbf{q}\mathbf{o}_{\mathbf{z}}^{\mathfrak{t}} = -\gamma \mathbf{o}_{\mathbf{z}}^{\mathfrak{t}} \mathbf{q}\mathbf{t} + \mathbf{q}\underline{z}^{\gamma \mathfrak{t}},$$

where $\lambda > 0$ and $z = \{ \bar{z}_t, t \ge 0 \}$ is a Lévy process with only positive increments (a subordinator).

• The risk-neutral dynamics of the log-price $Z_t = \log S_t$ are given by

$$dZ_t = (r - q - \lambda k(-\rho) - \sigma_t^2/2)dt + \sigma_t dW_t + \rho dz_{\lambda t}$$

- where $W = \{W_t, t \ge 0\}$ is a Brownian motion independent of $z = \{z_t, t \ge 0\}$ - $\mathcal{K}(u) = \log \mathbb{E}[\exp(-uz_1)]$ is cumulant function of z_1 .
- \bullet Note that the parameter ρ is introducing a correlation effect between the volatility and the asset

(9262-UO-smmsD) [9boM Z-NA 9dT

The Gamma-OU process:

• For this process $z = \{z_t, t \ge 0\}$ is a compound-Poisson process:

$$ux \stackrel{u}{\underset{1}{\overset{1}{\overset{1}{\overset{1}{\overset{1}{\overset{1}}}}}} = x} = z$$

– where $N = \{N_t, t \ge 0\}$ is a Poisson process with intensity parameter a, i.e. $E[N_t] = at;$ at;

- nsəm
ntiw wal laitnə
noqx H $_n$ follows a Exponential law with mean
 $- \{\lambda_n, 2, \ldots\}$ is a $\mathbb{E}_n, 2, \ldots\}$.
 $- [\lambda_n, 1]$
- $\sigma^2 = \{\sigma_t^2, t \ge 0\}$ is a stationary process with marginal law that follows a Gamma distribution with mean a and variance a/b: starting the process with an initial value sampled from this Gamma distribution, at each future time point t, σ_t^2 is also following that Gamma distribution.

$$\mathbf{F}(u+d)u\mathbf{n} = [(\mathbf{I}zu-)\mathbf{q}\mathbf{x}]\mathbf{H} = -au(b+1)\mathbf{h} \mathbf{h}$$

(9262-UO-smmsD) [9boM 2-NA 9dT

The characteristic function of the log-price process is given by

$$\begin{aligned} \phi(u,t) &= \mathcal{E}[\exp(\mathrm{i} u \log S_t) | S_0, \sigma_0] \\ &= \exp\left(\mathrm{i} u(\log(S_0) + (r - q - a\lambda\rho(-\lambda t))\sigma_0^2/2)\right) \\ &\times \exp\left(-\lambda^{-1}(u^2 + \mathrm{i} u)(1 - \exp(-\lambda t))\sigma_0^2/2\right) \\ &\times \exp\left(-\lambda^{-1}(u^2 + \mathrm{i} u)(1 - \exp(-\lambda t))\sigma_0^2/2\right) \\ & \times \exp\left(-\lambda^{-1}(u^2 + \mathrm{i} u)(1 - \mathrm{i} u)\right) \\ &\times \exp\left(-\lambda^{-1}(u^2 + \mathrm{i} u)(1 - \mathrm{i} u)\right) \\ &\times \exp\left(-\lambda^{-1}(u^2 + \mathrm{i} u)(1 - \mathrm{i} u)\right) \\ &\times \exp\left(-\lambda^{-1}(u^2 + \mathrm{i} u)(1 - \mathrm{i} u)\right) \\ & \times \exp\left(-\lambda^{-1}(u^2 + \mathrm{i} u)(1 - \mathrm{i} u)\right) \\ & \times \exp\left(-\lambda^{-1}(u^2 + \mathrm{i} u)(1 - \mathrm{i} u)\right) \\ & \times \exp\left(-\lambda^{-1}(u^2 + \mathrm{i} u)(1 - \mathrm{i} u)\right) \\ & \times \exp\left(-\lambda^{-1}(u^2 + \mathrm{i} u)(1 - \mathrm{i} u)\right) \\ & \times \exp\left(-\lambda^{-1}(u^2 + \mathrm{i} u)(1 - \mathrm{i} u)\right) \\ & \times \exp\left(-\lambda^{-1}(u^2 + \mathrm{i} u)(1 - \mathrm{i} u)\right) \\ & \times \exp\left(-\lambda^{-1}(u^2 + \mathrm{i} u)(1 - \mathrm{i} u)\right) \\ & \times \exp\left(-\lambda^{-1}(u^2 + \mathrm{i} u)(1 - \mathrm{i} u)\right) \\ & \times \exp\left(-\lambda^{-1}(u^2 + \mathrm{i} u)(1 - \mathrm{i} u)\right) \\ & \times \exp\left(-\lambda^{-1}(u^2 + \mathrm{i} u)(1 - \mathrm{i} u)\right) \\ & \times \exp\left(-\lambda^{-1}(u^2 + \mathrm{i} u)(1 - \mathrm{i} u)\right) \\ & \times \exp\left(-\lambda^{-1}(u^2 + \mathrm{i} u)(1 - \mathrm{i} u)\right) \\ & \times \exp\left(-\lambda^{-1}(u^2 + \mathrm{i} u)(1 - \mathrm{i} u)\right) \\ & \times \exp\left(-\lambda^{-1}(u^2 + \mathrm{i} u)(1 - \mathrm{i} u)\right) \\ & \times \exp\left(-\lambda^{-1}(u^2 + \mathrm{i} u)(1 - \mathrm{i} u)\right) \\ & \times \exp\left(-\lambda^{-1}(u^2 + \mathrm{i} u)(1 - \mathrm{i} u)\right) \\ & \times \exp\left(-\lambda^{-1}(u^2 + \mathrm{i} u)(1 - \mathrm{i} u)\right) \\ & \times \exp\left(-\lambda^{-1}(u^2 + \mathrm{i} u)(1 - \mathrm{i} u)\right) \\ & \times \exp\left(-\lambda^{-1}(u^2 + \mathrm{i} u)(1 - \mathrm{i} u)\right) \\ & \times \exp\left(-\lambda^{-1}(u^2 + \mathrm{i} u)(1 - \mathrm{i} u)\right) \\ & \times \exp\left(-\lambda^{-1}(u^2 + \mathrm{i} u)(1 - \mathrm{i} u)\right) \\ & \times \exp\left(-\lambda^{-1}(u^2 + \mathrm{i} u)(1 - \mathrm{i} u)\right) \\ & \times \exp\left(-\lambda^{-1}(u^2 + \mathrm{i} u)(1 - \mathrm{i} u)\right) \\ & \times \exp\left(-\lambda^{-1}(u^2 + \mathrm{i} u)(1 - \mathrm{i} u)\right) \\ & \times \exp\left(-\lambda^{-1}(u^2 + \mathrm{i} u)(1 - \mathrm{i} u)\right) \\ & \times \exp\left(-\lambda^{-1}(u^2 + \mathrm{i} u)(1 - \mathrm{i} u)\right) \\ & \times \exp\left(-\lambda^{-1}(u^2 + \mathrm{i} u)\right) \\ & \times \exp\left(-\lambda^{-1}(u^2 + \mathrm{i} u)(1 - \mathrm{i} u)\right) \\ & \times \exp\left(-\lambda^{-1}(u^2 + \mathrm{i} u)(1 - \mathrm{i} u)\right) \\ & \times \exp\left(-\lambda^{-1}(u^2 + \mathrm{i} u)(1 - \mathrm{i} u)\right) \\ & \times \exp\left(-\lambda^{-1}(u^2 + \mathrm{i} u$$

мубте

$$f_{1} = f_{1}(u) = iu\rho - \lambda^{-1}(u^{2} + iu)(1 - \exp(-\lambda t))/2,$$

Stochastic Volatility Lévy Models (CGMY 2001)

To build in stochastic volatility, we can also make time stochastic.

- We increase or decrease the level of uncertainty by speeding up or slowing down the rate at which time passes.
- To build clustering and to keep time going forward we employ a mean-reverting positive process y_t as a measure of the local rate of time change.
- ullet The economic time elapsed in t units of calender time is then given by Y(t) where

 $s \mathbf{p}^s \boldsymbol{h} \stackrel{0}{\to} = (\mathbf{i}) X$

There are different candidates for the time change:

$$dMp_{7/I} + \gamma p(\ell - h) = \kappa (\mu - \mu) \gamma$$

 \bullet OU-processes , i.e. the stationary process satisfying the SDE:

$$d^{4} = -\gamma h^{4} q + q z^{\gamma 4}$$

where z_t is a subordinator.

Stochastic Volatility Lévy Models

- The characteristic function ϕ of Y(t) is explicitly known for:
- -the CIR-process,
- -the Gamma-OU process: $y_t \sim Gamma$,
- -the IG-OU Process: $y_t \sim IG$.
- \bullet We now model our (risk-neutral) price process S_t as follows:

$$({}^{(i)}_{A}X) \mathrm{dx}_{\partial} \frac{[({}^{(i)}_{A}X) \mathrm{dx}_{\partial}]_{\mathcal{I}}}{(i(b-i)) \mathrm{dx}_{\partial}} S = {}^{i}_{S} S$$

where X_t is a Lévy process with

$$E[\exp(in X\psi t) \operatorname{qxs} = [(iXui) \operatorname{qxs}]$$

• The characteristic function for the log of our stock price is given by:

$$\frac{(t,(i)_X\psi i-)\phi}{(i,(i)_X\psi i-)\phi}({}_0S\operatorname{gol} + t(p-\tau))ui)qx9 = [((i,N)_X\psi i-)\phi](2i)qx9$$

Simulation of the CIR Process

We discretize the SDE

$$\mathrm{d}y_t = \kappa(\eta - y_t)\mathrm{d}t + \lambda y_t^{1/2}\mathrm{d}W_t, \quad y_0 \ge 0.$$

The sample path of the CIR process $y = \{y_t, t \ge 0\}$ in the time points $t = n\Delta t$, $n = 0, 1, 2, \ldots$, is then given by

$$u^{n} \overline{\partial \Delta \nabla} \sqrt{2\Delta (1-n)} \psi (\lambda + D \Delta (1-n) \psi - \eta) + \lambda \Delta (1-n) \psi = \lambda \Delta \eta$$

where $\{v_n, n = 1, 2, \ldots\}$ is a series of independent standard Normal random numbers.

Figure 12: Simulation of CIR-process

Simulation of a Gamma(a, b)-OU process $y = \{y_t, t \ge 0\}$ in the time points $t = n\Delta t$, $1, 2, \ldots$:

- simulate in the same time points a Poisson process $N = \{N_t, t \ge 0\}$ with intensity parameter $a\lambda$;
- , eries a series of independent Uniform random numbers; \bullet
- let x_n be exponential random numbers : $x_n = -\log(u_n)/b$, where u_n are a series of independent Uniform random numbers;
- then (with the convention that a empty sum equals zero)

$$\cdot (_{n}\tilde{u}t\Delta \Lambda -) \operatorname{qxs}_{n} x \operatorname{dx}_{1+_{t\Delta(1-n)}N=n} + _{t\Delta(1-n)} \psi(t\Delta \Lambda - 1) = _{t\Delta n}\psi$$

Simulation of the Gamma-OU Process

Figure 13: Simulation of Gamma-OU process

Simulation of the NIG-Lévy Process

Simulation of a NIG(α, β, δ) process $X = \{X_t, t \ge 0\}$ in the time points $t = n\Delta t$, Σ, \ldots :

- First simulate $IG(\delta, \sqrt{\alpha^2 \beta^2})$ random numbers i_k by for example using the Inverse Gaussian generator of Michael, Schucany and Haas.
- Then sample a sequence of standard Normal random variable u_k .
- NIC random numbers n_k are then obtain by:

$$\exists u_{\underline{A}} i \underline{V} + A i \underline{U} = A u$$

Figure 14: Simulation of NIG process

Moment Derivatives

- We have a clear issue of model risk.
- We push this study a little bit further by looking at moment derivatives¹.
- Their payoff is a function of powers of the (daily) log-returns and allow to cover different kinds of market shocks.
- \bullet Variance swaps were already created to cover changes in the volatility regime.
- However skewness and kurtosis, also play an important role. To protect against a wrongly estimated skewness or kurtosis, moment derivatives of higher order can be useful.
- Recent theoretical work (Corcuera-Nualart-S, 2004) shows that moment assets are the instruments which can naturally complete a Lévy driven market.

Moment Swaps

- Consider a finite set of discrete times $\{t_0 = 0, t_1, \ldots, t_n = T\}$ at which the path of the underlying is monitored.
- Denote the price of the underlying at these points, i.e. S_{t_i} , by S_i for simplicity.
- The kth-moment swap is a contract where the parties agree to exchange at maturity:

where N is the nominal amount.

• Variance Swap:

- \bullet MOMS^{(3)} is related to realized skewness and provides protection against changes in the symmetry of the underlying distribution.
- \bullet $MOMS^{(4)}$ derivatives are linked to realized kurtosis and provide protection against the unexpected occurences of very large jumps

$$(1-i)SWOW \xrightarrow{i=i}{U} (\nabla E^{i} / E^{i-1}) = O(\sum_{u}^{i=i} (\nabla E^{i} / E^{i-1}) + O(\sum_{u}^{i=i} (\nabla E^{i} / E^{i-1}) + O(E^{i}) = O(E^{i}) = O(E^{i})$$

$$(1-i)SWOW \xrightarrow{i=i}{U} = O(E^{i}) = O(E^{i}) = O(E^{i})$$

$$(1-i)SWOW = O(E^{i}) = O(E^{i}) = O(E^{i})$$

$$(1-i)SWOW = O(E^{i})$$

$$(1-i)SWW =$$

. Hoved ${}^{(k)}SMOM$ of the motification of the $MOMS^{(k)}$ payoff:

• Substituting x by
$$F_i / F_{i-1}$$
 leads to:

$$(\log(F_i / F_{i-1}))^k = k! \left(\frac{\Delta F_i}{F_{i-1}} - \log(F_i / F_{i-1}) - \sum_{j=2}^{k-1} (\log(F_i / F_{i-1}))^j + \mathcal{O}((\Delta F_i / F_{i-1}))^j, + \mathcal{O}((\Delta F_i / F_{i-1}))^j),$$
where $\Delta F_i = F_i - F_{i-1}$.

$$(^{1+\lambda}(1-x))O + \frac{^{1-\lambda}((x)gol)}{!(1-\lambda)} - \dots - \frac{^{1-\lambda}((x)gol)}{!(1-\lambda)} - \frac{^{1-\lambda$$

Hedging Moment Swaps-1 • We use the following (Taylor-like) expansion of the kth power of the logarithmic function and work with swaps with future prices $F_i = \exp((r-q)(T-t_i))S_i$ as underlying:

C-sqswS tnemoM guigbeH

- Thus up to (k + 1)th-order terms the sum of the kth powered log-returns decomposes
- $a \text{ log-contract } (-\mathcal{K}! (\log(F_T) \log(F_0))); \\ a \text{ dynamic strategy } (\mathcal{K}! \sum_{i=1}^{n} \frac{\Delta F_i}{F_{i-1}}); \\ a \text{ dynamic strategy } (\mathcal{K}! \sum_{i=1}^{n} \frac{\Delta F_i}{F_{i-1}}); \\ a \text{ dynamic strategy } (\mathcal{K}! \sum_{i=1}^{n} \frac{\Delta F_i}{F_{i-1}}); \\ a \text{ dynamic strategy } (\mathcal{K}! \sum_{i=1}^{n} \frac{\Delta F_i}{F_{i-1}}); \\ a \text{ dynamic strategy } (\mathcal{K}! \sum_{i=1}^{n} \frac{\Delta F_i}{F_{i-1}}); \\ a \text{ dynamic strategy } (\mathcal{K}! \sum_{i=1}^{n} \frac{\Delta F_i}{F_{i-1}}); \\ a \text{ dynamic strategy } (\mathcal{K}! \sum_{i=1}^{n} \frac{\Delta F_i}{F_{i-1}}); \\ a \text{ dynamic strategy } (\mathcal{K}! \sum_{i=1}^{n} \frac{\Delta F_i}{F_{i-1}}); \\ a \text{ dynamic strategy } (\mathcal{K}! \sum_{i=1}^{n} \frac{\Delta F_i}{F_{i-1}}); \\ a \text{ dynamic strategy } (\mathcal{K}! \sum_{i=1}^{n} \frac{\Delta F_i}{F_{i-1}}); \\ a \text{ dynamic strategy } (\mathcal{K}! \sum_{i=1}^{n} \frac{\Delta F_i}{F_{i-1}}); \\ a \text{ dynamic strategy } (\mathcal{K}! \sum_{i=1}^{n} \frac{\Delta F_i}{F_{i-1}}); \\ a \text{ dynamic strategy } (\mathcal{K}! \sum_{i=1}^{n} \frac{\Delta F_i}{F_{i-1}}); \\ a \text{ dynamic strategy } (\mathcal{K}! \sum_{i=1}^{n} \frac{\Delta F_i}{F_{i-1}}); \\ a \text{ dynamic strategy } (\mathcal{K}! \sum_{i=1}^{n} \frac{\Delta F_i}{F_{i-1}}); \\ a \text{ dynamic strategy } (\mathcal{K}! \sum_{i=1}^{n} \frac{\Delta F_i}{F_{i-1}}); \\ a \text{ dynamic strategy } (\mathcal{K}! \sum_{i=1}^{n} \frac{\Delta F_i}{F_{i-1}}); \\ a \text{ dynamic strategy } (\mathcal{K}! \sum_{i=1}^{n} \frac{\Delta F_i}{F_{i-1}}); \\ a \text{ dynamic strategy } (\mathcal{K}! \sum_{i=1}^{n} \frac{\Delta F_i}{F_{i-1}}); \\ a \text{ dynamic strategy } (\mathcal{K}! \sum_{i=1}^{n} \frac{\Delta F_i}{F_{i-1}}); \\ a \text{ dynamic strategy } (\mathcal{K}! \sum_{i=1}^{n} \frac{\Delta F_i}{F_{i-1}}); \\ a \text{ dynamic strategy } (\mathcal{K}! \sum_{i=1}^{n} \frac{\Delta F_i}{F_{i-1}}); \\ a \text{ dynamic strategy } (\mathcal{K}! \sum_{i=1}^{n} \frac{\Delta F_i}{F_{i-1}}); \\ a \text{ dynamic strategy } (\mathcal{K}! \sum_{i=1}^{n} \frac{\Delta F_i}{F_{i-1}}); \\ a \text{ dynamic strategy } (\mathcal{K}! \sum_{i=1}^{n} \frac{\Delta F_i}{F_{i-1}}); \\ a \text{ dynamic strategy } (\mathcal{K}! \sum_{i=1}^{n} \frac{\Delta F_i}{F_{i-1}}); \\ a \text{ dynamic strategy } (\mathcal{K}! \sum_{i=1}^{n} \frac{\Delta F_i}{F_{i-1}}); \\ a \text{ dynamic strategy } (\mathcal{K}! \sum_{i=1}^{n} \frac{\Delta F_i}{F_{i-1}}); \\ a \text{ dynamic strategy } (\mathcal{K}! \sum_{i=1}^{n} \frac{\Delta F_i}{F_{i-1}}); \\ a \text{ dynamic strategy } (\mathcal{K}! \sum_{i=1}^{n} \frac{\Delta$
- a series of moment contracts of order strictly smaller than k.
- The log-contract itself can be hedged by a static position in the underlying, in a bond and in a (discrete approximation of a continuous) set of European vanilla call and put options maturing at time T (Carr-Lewis).
- \bullet Note that

$$LOG = \exp(-rT) \mathcal{E}_Q[\log(S_T) - \log(S_0)] \mathcal{F}_Q[\log(S_T) - \log(S_0)] \mathcal{F}_Q]$$

Hence:

$$LOG_{hest} = \exp(-rT)\left(rT + \frac{2b\lambda}{2}\left((a - b\sigma_0^2)(1 - e^{-\lambda T}) - a\lambda T(1 + 2\lambda\rho^2(b - \rho)^{-1})\right)\right)$$
$$LOG_{hest} = \exp(-rT)\left(rT + \frac{1}{2}\left[Y_T\right]E[X_1] - \log(E[\exp(X_{Y_T})])\right)$$

Moment Options

• Related to the above discussed swaps, we define the associated options on the realized kth moment. More precisely, a *moment option* of order k, pays out at maturity T:

$$\cdot \left(X - {}^{A}(({}^{I-i}S/{}^{i}S)\operatorname{gol}) \underset{I=i}{\overset{a}{\searrow}} \right)$$

 \bullet The price of these options under risk-neutral valuation is given by:

$$MOMO^{(k)}(K,T) = \exp(-rT)E_Q \left[\left(\prod_{i=1}^n (\log(S_i/S_i) \otimes D_i \otimes D_i) \right)_{I=i}^n \right] = \exp(-rT) + \exp(-rT$$

• Note that since odd moments can be negative, the strike price for these options can range over the whole real line.

Conclusion

- The Black-Scholes model does not correspond with reality.
- Moreover, Black-Scholes- exotic option prices depend heavily one the choice of the volatility parameter and it is not clear which value to take.
- More advanced Lévy process-based models give a very accurate fit to real market option
- \bullet Monte-Carlo simulation for these models is possible.
- Prices of exotics however can differ significantly over different attractive models.
- We have a clear issue of model risk.
- We have push thius study further by pricing moment derivatives.
- \bullet Moment derivatives are related to realized higher moments.
- Hedging aspects of moment swaps were discussed.
- By pricing moment swaps and moment options, we have shown that the disparity between the models is amplified.
- More detailed studies are needed in order to differentiate between the models.
